May 13, 2020

1 Introduction

In this paper, I will formally describe the typing rule of Baremetalisp, which is a well typed Lisp for trusted execution environment.

2 Notation and Syntax

Table 1 and Fig. 1 shows notation used in this paper and syntax for the typing rule, respectively.

Listing 1: Example of variable and type

```
(defun add (a b) (Pure (-> (Int Int) Int))
    (+ a b))
```

x is a variable. For example, $x \in \{a, b\}$ in Listing 1. $\mathcal{T}$ is a type. For example, $\mathcal{T} \in \{\texttt{Int}, (\rightarrow\ (\texttt{Int Int})\ \texttt{Int})\}$ in Listing 1. $(\rightarrow\ (\texttt{Int Int})\ \texttt{Int})$ is a function type which takes 2 integer values and return 1 integer value. `Pure` in Listing 1 denotes the effect of the function but I just ignore it now. Function effects will be described in Sec. 4. $\mathcal{T}$ can be other forms as described in Fig. 1 such as `Bool`, $'(\texttt{Int})$, $[\texttt{Bool Int}]$, $(\text{List } a)$, $(\text{List } \texttt{Int})$. C is a type constraint, which is a set of pairs of types. For example, $C = \{(\rightarrow\ (t_1\ t_2)\ t) = (\rightarrow\ (\texttt{Int Int})\ \texttt{Int})\}$ deduced from Listing 1 means $(\rightarrow\ (t_1\ t_2)\ t)$ and $(\rightarrow\ (\texttt{Int Int})\ \texttt{Int})$ are semantically equal and every type variable in C, t_1, t_2, t, is thus `Int`. Γ is a map from variable and label to type. For example, $\Gamma = \{a : t_1, b : t_2, + : (\rightarrow\ (\texttt{Int Int})\ \texttt{Int})\}$ in Listing 1. Γ is called context generally, thus I call Γ context in this paper.

Listing 2: Example of user defined data type

```
(data (List a)
    (Cons a (List a))
    Nil)
```

t is a type variable. For example, $t \in \{a\}$ in Listing 2. L is a label for user defined type. For example, $L \in \{\text{Cons}, \text{Nil}\}$ in Listing 2. D is user defined data. For example, $D \in \{\text{List}\}$ in Listing 2. Γ will hold mapping from labels in

Table 1: Notation

e	expression
z	integer literal such as 10, -34, 112
x	variable
t	type variable
D	type name of user defined data
L	label of user defined data
$\mathcal{T}$	type
C	type constraint
Γ	context
$\mathcal{P}$	pattern
$\mathcal{P}_{let}$	pattern of let expression
$\mathcal{T}_1 \equiv_\alpha \mathcal{T}_2$	$\mathcal{T}_1$ and $\mathcal{T}_2$ are α-equivalent
$\mathcal{S} : t \to \mathcal{T}$	substitution from type variable to type
$\mathcal{T} \cdot \mathcal{S}$	apply $\mathcal{S}$ to $\mathcal{T}$
$\mathcal{X}$	set of t
$FV_{\mathcal{T}} : \mathcal{T} \to \mathcal{X}$	function from $\mathcal{T}$ to its free variables
$FV_{\Gamma} : \Gamma \to \mathcal{X}$	function from Γ to its free variables
$Size : L \to \texttt{Int}$	the number of labels L's type has
$\Gamma \vdash e : \mathcal{T} \mid_{\mathcal{X}} C$	e's type is deduced as $\mathcal{T}$ from Γ under constraint C and type variables $\mathcal{X}$

addition to variables. For example, $\Gamma = \{\mathrm{Cons} : (\mathrm{List}\ a), \mathrm{Nil} : (\mathrm{List}\ a), \mathrm{Cons}_{1st} : a, \mathrm{Cons}_{2nd} : (\mathrm{List}\ a)\}$ in Listing 2.

$FV_{\mathcal{T}}$ and FV_{Γ} are functions, which take $\mathcal{T}$ and Γ and return free variables. For example, $FV_{\mathcal{T}}((\to\ (t_1\ t_2)\ t)) = \{t_1, t_2, t\}$ and

$$\begin{aligned}
&FV_{\Gamma}(\{a : t_1, b : t_1, + : (\to\ (\texttt{Int Int})\ \texttt{Int})\}) \\
&= \{FV_{\mathcal{T}}(t_1), FV_{\mathcal{T}}(t_1), FV_{\mathcal{T}}((\to\ (\texttt{Int Int})\ \texttt{Int}))\} \\
&= \{t_1, t_2\}.
\end{aligned}$$

$\mathcal{T}_1 \equiv_\alpha \mathcal{T}_2$ denotes that $\mathcal{T}_1$ and $\mathcal{T}_2$ are α-equivalent, which means $\mathcal{T}_1$ and $\mathcal{T}_2$ are semantically equal. For example, $(\to\ (t_1\ t_2)\ t) \equiv_\alpha (\to\ (t_{10}\ t_{11})\ t_{12})$. $\mathcal{S}$ is a substitution, which is a map from type variable to type, and it can be applied to $\mathcal{T}$ as $\mathcal{T} \cdot \mathcal{S}$. For example, if $\mathcal{S}(t_1) = [\texttt{Bool Int}], \mathcal{S}(t_2) = (\mathrm{List}\ t_3)$ then $(\to\ (t_1\ t_2)\ t) \cdot \mathcal{S} = (\to\ ([\texttt{Bool Int}]\ (\mathrm{List}\ t_3))\ t)$.

Listing 3: Example of pattern matching

```
(data Dim2 (Dim2 Int Int))

(data (Maybe t)
    (Just t)
    Nothing)

(defun match-let (a) (Pure (-> ((Maybe Dim2)) Int))
    (match a
        ((Just val)
```

$\mathcal{C}$	$:=$	$\mathcal{T} = \mathcal{T}, \mathcal{C}$	**type constraint**
	$\mid$	$\varnothing$	
Γ	$:=$		**context**
		$x : \mathcal{T}, \Gamma$	type of variable
	$\mid$	$L : \mathcal{T}, \Gamma$	type of label
	$\mid$	$L_{nth} : \mathcal{T}, \Gamma$	n-th type of label's element
	$\mid$	$\varnothing$	
$\mathcal{T}$	$:=$		**type**
		`Int`	
	$\mid$	`Bool`	
	$\mid$	$'(\mathcal{T})$	list type
	$\mid$	$[\mathcal{T}+]$	tuple type
	$\mid$	D	user defined type
	$\mid$	$(D\ \mathcal{T}+)$	user defined type with type arguments
	$\mid$	$(\rightarrow\ (\mathcal{T}*)\ \mathcal{T})$	function type
	$\mid$	t	type variable
$\mathcal{P}$	$:=$		**pattern**
		x	variable
	$\mid$	L	label
	$\mid$	$(L\ \mathcal{P}+)$	label with patterns
	$\mid$	$'()$	empty list
	$\mid$	$[\mathcal{P}+]$	tuple
$\mathcal{P}_{let}$	$:=$		**patten for let**
		x	variable
	$\mid$	$(L\ \mathcal{P}_{let}+)$	label with patterns
	$\mid$	$[\mathcal{P}_{let}+]$	tuple

Figure 1: Syntax

```
10            (let (((Dim2 x y) val))
11                (+ x y)))
12        (Nothing
13            0)))
```

$\mathcal{P}$ and $\mathcal{P}_{let}$ are pattern in match and let expressions. For example, in listings 3, *(Just val)* and *Nothing* at line 9 and 12 are from $\mathcal{P}$ and *(Dim2 x y)* at line 10 is from $\mathcal{P}_{let}$. *Size* is a function which takes a label and return the number of labels the label's type has. For example, $Size(\text{Just}) = Size(\text{Nothing}) = 2$ because Maybe type has 2 labels and $Size(\text{Dim2}) = 1$ because Dim2 type has 1 label in listings 3.
